

# AquaQuarantine: kdb+ in a containerised solution

Experts in fast data solutions  
for demanding environments

- Established in 2011
- Headquarters in Belfast, N.Ireland
- Headcount of 160 staff
- 2016 US Subsidiary launched
- 2018 Singapore subsidiary launch
- 2020 Hong Kong subsidiary launch

## What do we do?

Technology  
Consultancy Services

Altair Panopticon  
Professional Services

Remote (24/7) Support  
Centre of Excellence

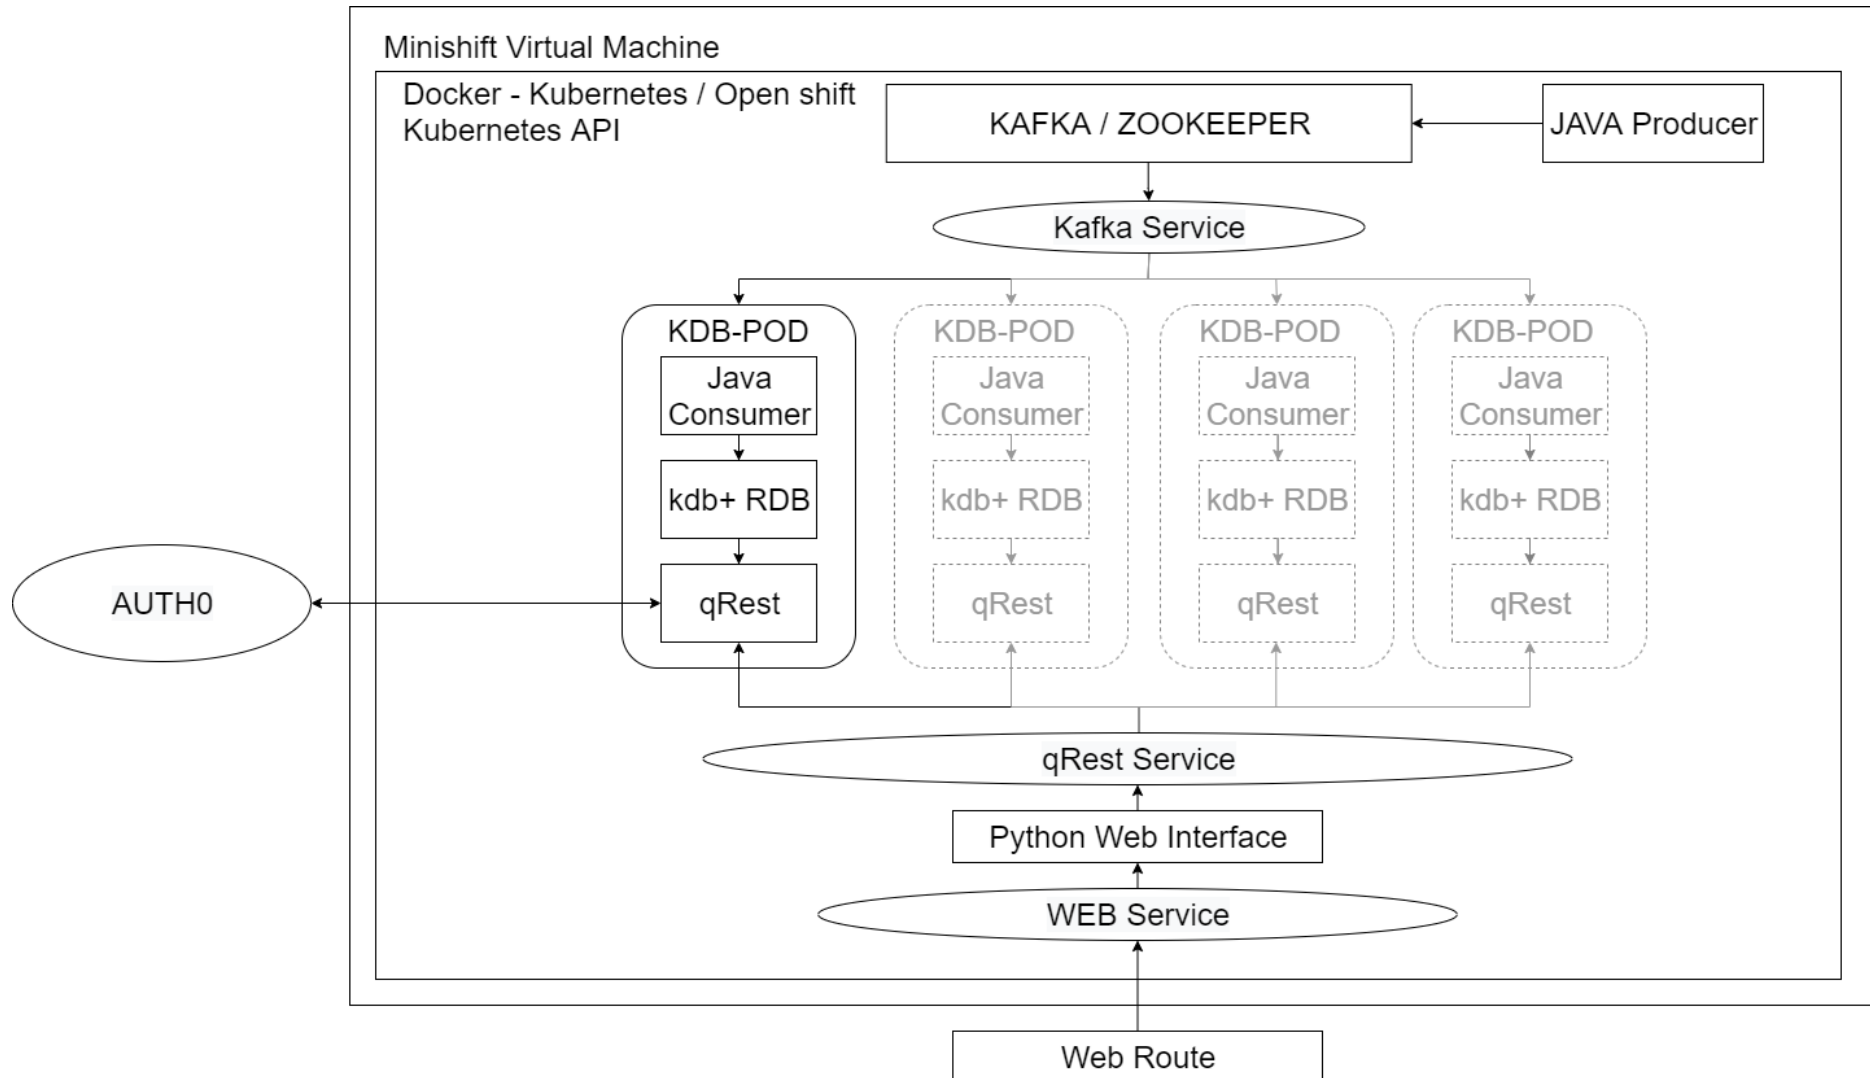

# Objective

The proof of concept is to demonstrate the following capabilities:

- kdb+ in containers
- Entitlements interaction with kdb+ in containers
- Integration of kdb+ containers within data pub sub setup

# Architecture

# Technologies

Technology [Version]	Function
Minishift	Virtual Machine running full OKD Cluster
Openshift [3.11] Kubernetes [1.11] Docker	Containers and container management
AUTH0	Authentication and user role management
kdb+	Real-time database
Springboot Java	<ul style="list-style-type: none"> <li>• Data generation (quote/trade)</li> <li>• Push to Kafka topics (1 per dataset)</li> <li>• Data consumption and push to kdb+ (Feedhandler)</li> </ul>
Python JS / HTML /CSS	Web front end
Kafka	Message handling system
qRest	<ul style="list-style-type: none"> <li>• Open Source Restful Interface for kdb</li> <li>• Modified for token handling</li> </ul>

# Roles & Entitlements

Roles, entitlements and authentications through AUTH0 (<https://auth0.com/>)

User	Role	Description
<a href="mailto:demo0@aquaq.co.uk">demo0@aquaq.co.uk</a>	realtime	Full access to all data in real time
<a href="mailto:demo1@aquaq.co.uk">demo1@aquaq.co.uk</a>	delay_15	Access to data provided it is >=15 minutes old (Time filtering)
<a href="mailto:demo2@aquaq.co.uk">demo2@aquaq.co.uk</a>	delay_05, xlon	Access to only London data and aged >=5 minutes (Row and Time filtering)
<a href="mailto:demo3@aquaq.co.uk">demo3@aquaq.co.uk</a>	delay_05, xams, xmil	Access to only Amsterdam and Milan data, aged >=5 minutes
<a href="mailto:demo4@aquaq.co.uk">demo4@aquaq.co.uk</a>	no_ex	User is not allowed to see the exchange data and therefore it's columns are not visible (Column filtering)
<a href="mailto:demo5@aquaq.co.uk">demo5@aquaq.co.uk</a>	no_trade	User cannot see the trade table (Table filtering)

# q-REST

kdb+ queries are through the q-REST API (<https://www.aquaq.co.uk/q/q-rest/>). This has been modified to handle tokens.

- Simple RESTful web services
- Integration from any client
- Connects to any kdb+ database
- Seamless integration with TorQ
- Supports synchronous and deferred sync connections for concurrency

<https://github.com/AquaQAnalytics/q-REST>

# Demo

kdb-containers PoC

log in

# Success Criteria

Scenario	Comments
Simulated market data will be generated in the publisher	✓ PoC uses Java/Springboot container
Publisher will publish data onto a Kafka Topic	<ul style="list-style-type: none"> <li>✓ Kafka topic per dataset trade/quote</li> <li>✓ Publisher sends to appropriate topic</li> </ul>
RDB will consume data from the Kafka Topic	<ul style="list-style-type: none"> <li>✓ RDB consumes via Java Feedhandler (FH)</li> <li>✓ RDB and FH are housed in replicable pod</li> <li>✓ Pods allows for horizontal scalability</li> </ul>
Subscriber will simulate connection from querying client	<ul style="list-style-type: none"> <li>✓ Python web front end with q-<b>Rest</b> integration</li> <li>✓ Querying client read-only</li> </ul>
Subscriber will simulate connection from a client subscription	<ul style="list-style-type: none"> <li>✓ UI interface allows for polling based subscription</li> <li>✓ Client applications should consume from kafka</li> </ul>
Subscriber subject to authentication	<ul style="list-style-type: none"> <li>✓ Role based access via AUTH0</li> <li>✓ Single entry point, no kdb+ ports exposed</li> </ul>
Entitlements demonstration against kdb+ service	✓ Users have roles determining data access
Chaos scenario, overloaded RDB	✓ RDB Crashes, comes back up as went inactive

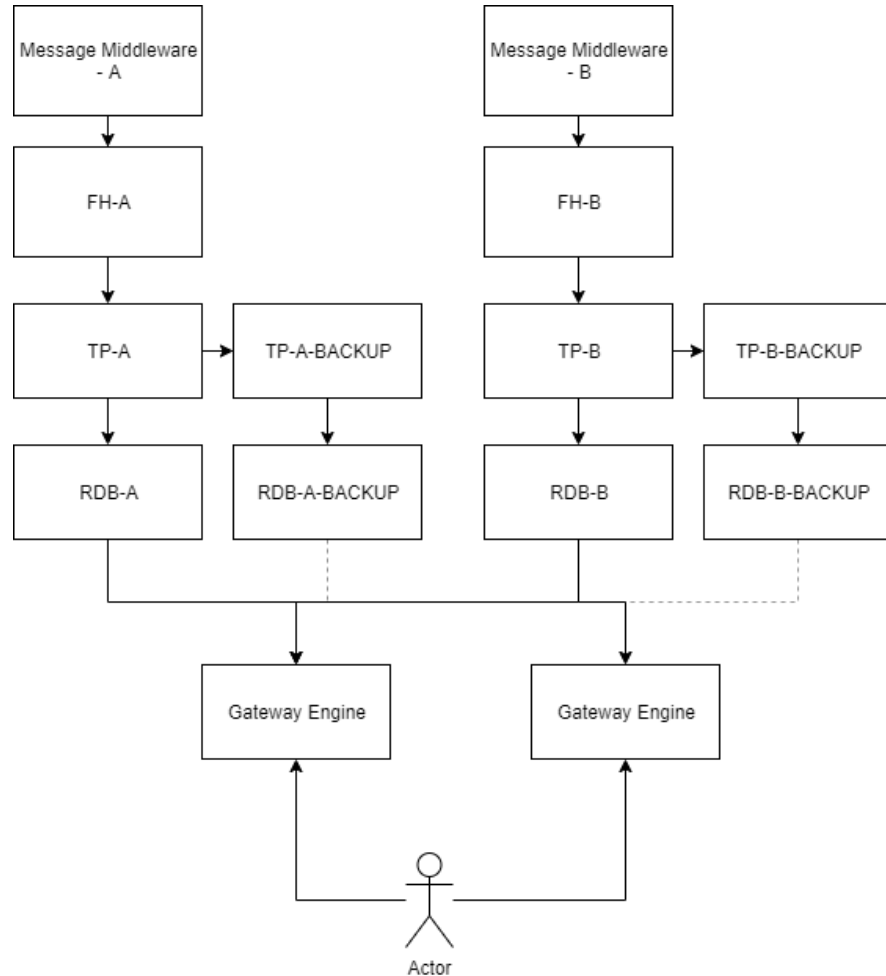

# Containerised vs Non

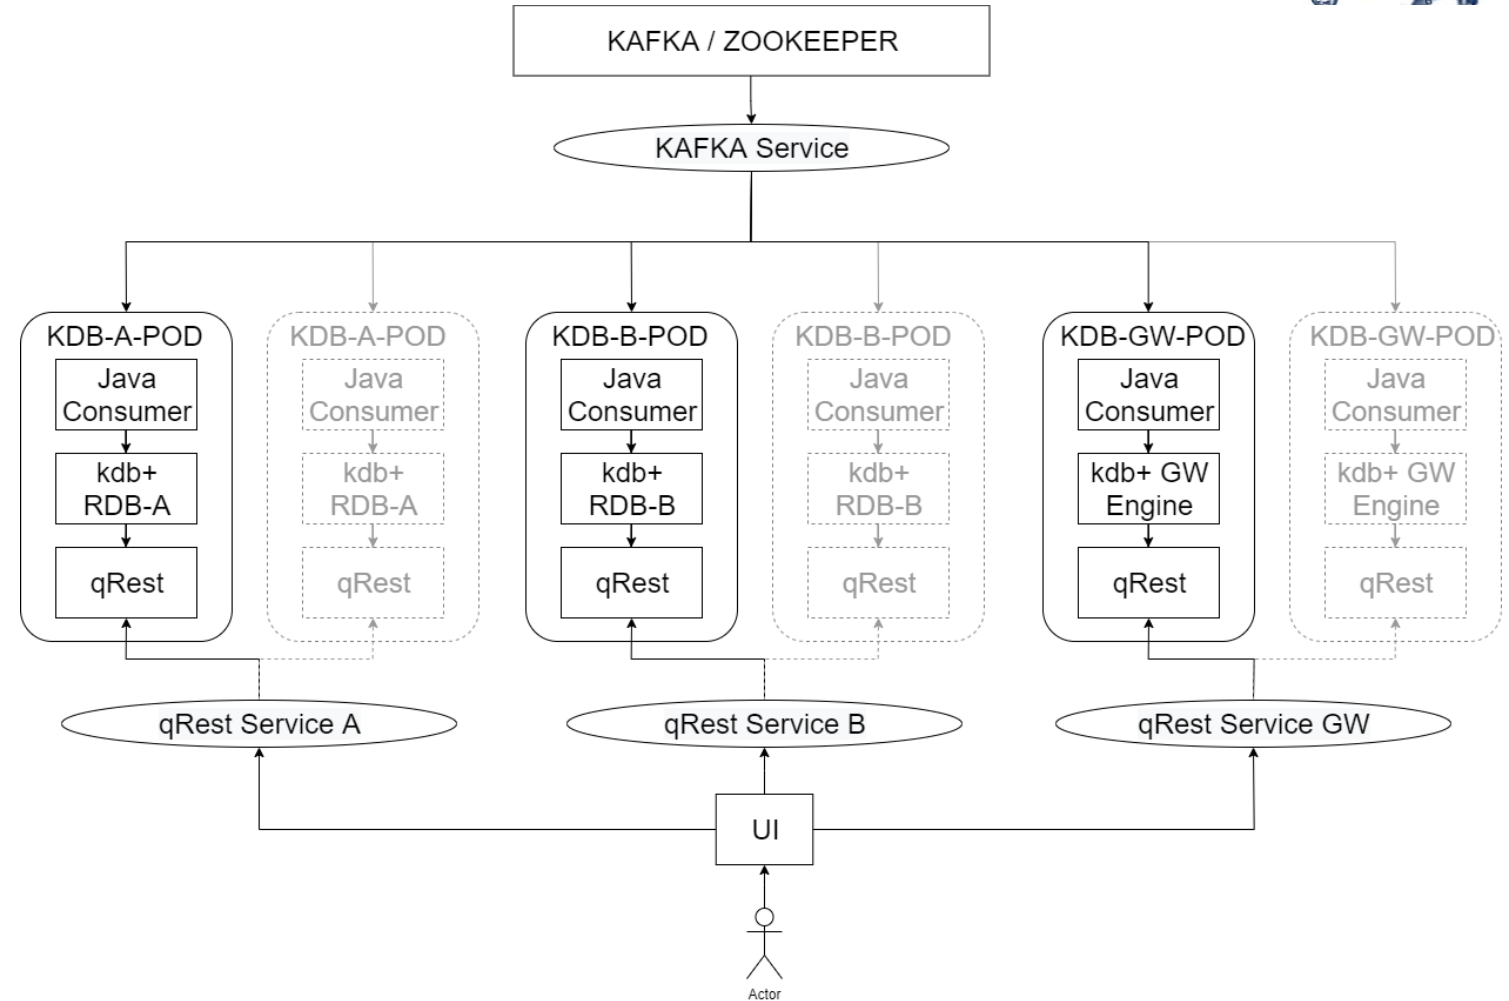

Characteristic	Containerised	Non-Containerised
Architecture	<ul style="list-style-type: none"> <li>• Potential to simplify through no tickerplants, kafka direct replay</li> <li>• Consumption from Kafka, rather than kdb+ -&gt; kdb+</li> <li>• Current kdb implementations would need re-defined</li> </ul>	<ul style="list-style-type: none"> <li>• Typical kdb tick architecture</li> </ul>
Resources	<ul style="list-style-type: none"> <li>• Reduced CPU consumption due to tickerplant removal</li> <li>• Reduced disk usage due to no tickerplant log</li> <li>• Memory footprint of RDB the same</li> </ul>	
Scalability	<ul style="list-style-type: none"> <li>• qRest provides a single entry point to access all available pods</li> <li>• Pods can be scaled for additional RDBs</li> <li>• Pod monitoring can ensure n number of pods are active</li> </ul>	<ul style="list-style-type: none"> <li>• Chained tickerplants and RDBs would be required, these require manual interaction and configuration with additional monitoring added</li> </ul>
Recoverability	<ul style="list-style-type: none"> <li>• Pods can be spawned easily and automatically without need for user switching</li> <li>• Recovery time will still be dependent on amount of messages to consume</li> </ul>	<ul style="list-style-type: none"> <li>• Requires manual intervention and user notification/impact without additional architecture (Gateways)</li> <li>• Recovery time dependent on amount of messages to consume</li> </ul>

# A Potential Re-Architecture

Typical

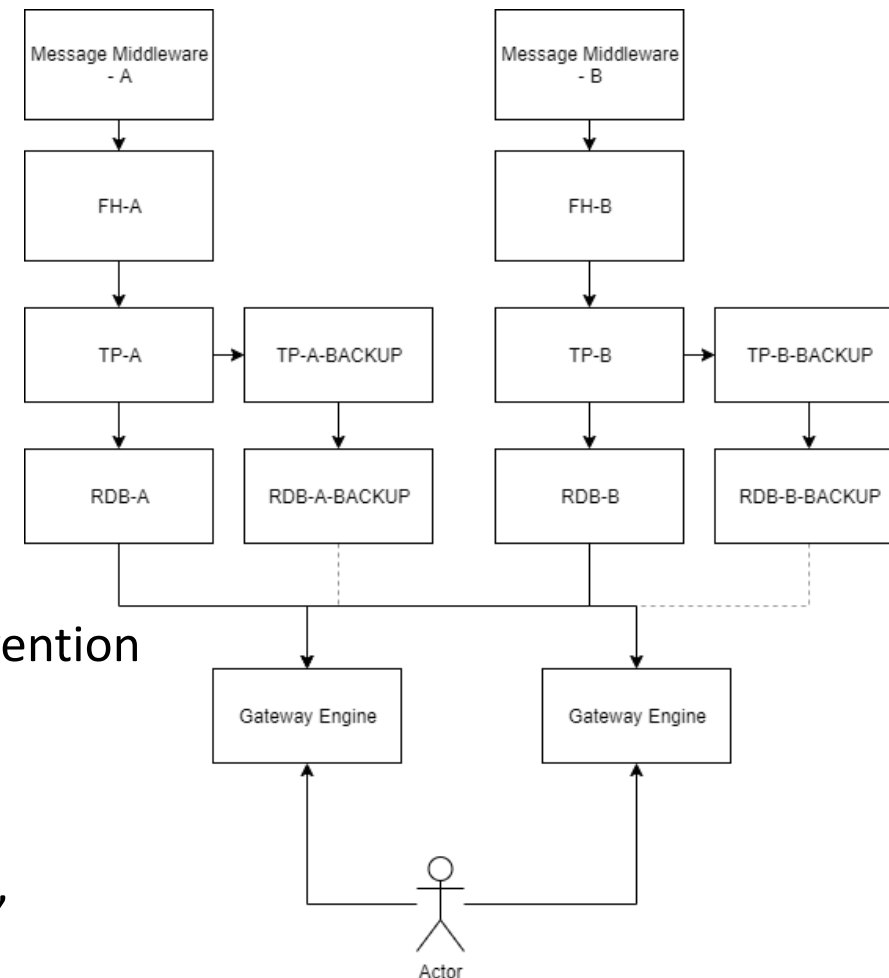

Containerized

# Potential Re-Architecture: Typical

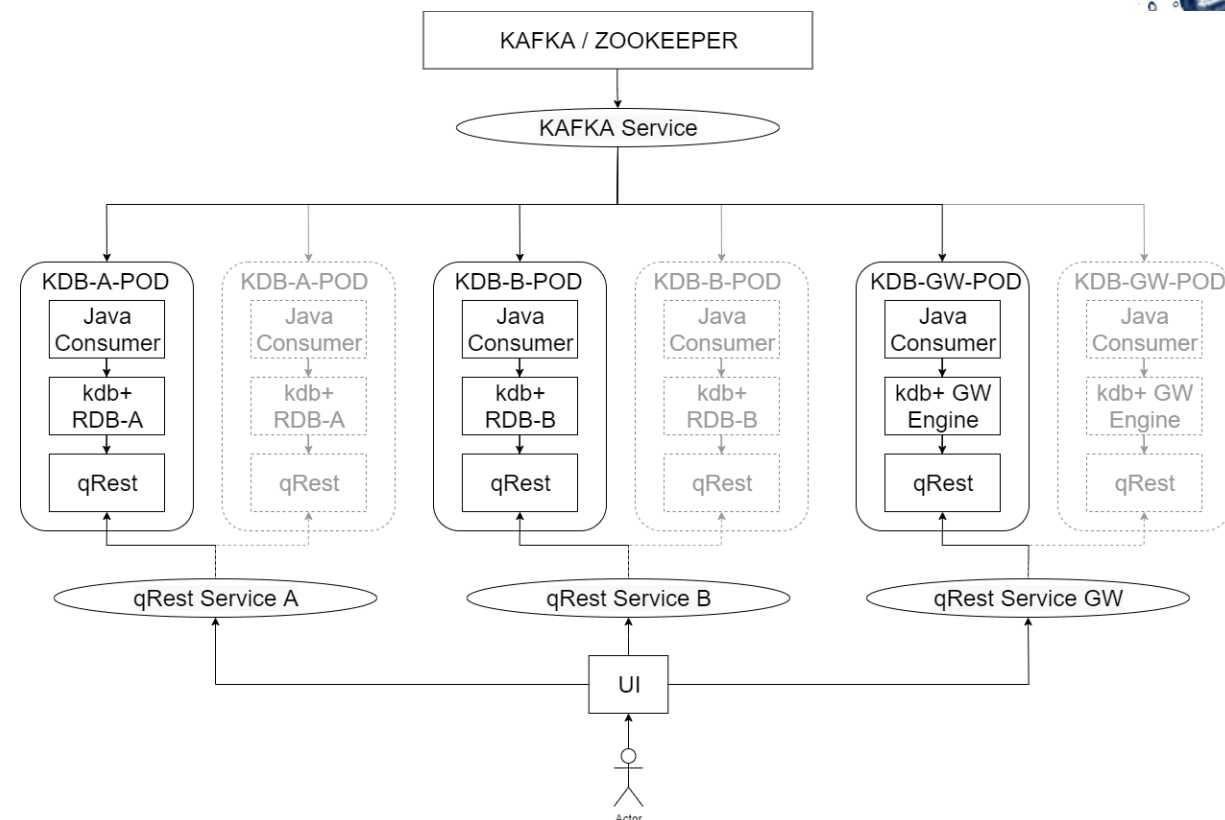

- Individually managed and supported components
- Open access to all elements
- No scalability without config/code implementation
- Chained Tickerplants connected to main chain
- Susceptible to change in server configuration
- Migration across hardware is difficult
- Many potential points of failure (TP/RDB/GW/FH)
- Loss of TP results in full chain failure
- Loss of RDB impacts GW and requires manual intervention
- Access to RDBs could impact users on GW
- Manual restart of elements in any failure
- kdb+ upgrade requires interaction with all elements, dependencies and clients of each element.

# Potential Re-Architecture: Typical

- Pods managed through Openshift
- Single entry point to each kdb+ through qRest endpoints.
- No open access to kdb+ processes
- No chained tickerplants, each pod is independent
- Instant scalability
- Migration is simplified (no server specific config)
- Microservice architecture (auto recovery of pods)
- No Tickerplant, recovery from Kafka
- No Tickerplant, no risk of slow consumer
- GW is separate, if RDB goes down no impact.
- Potential increased memory/data duplication by separating GW

# Potential Re-Architecture: Typical

- kdb+ in containers
  - Scalable
  - Recoverable
  - Server Agnostic
  - Secure
- Entitlements interaction with kdb+ in containers
  - Single entry point
  - Unit of deployment/access is now pod not individual kdb+ process
- Integration of kdb+ containers within data pub sub setup
  - Integration with kafka
  - Potential removal of tickerplant
  - Integration with Restful interface

Thanks!
